CARBON™ ALLIANCE

Generate Ag Carbon Credits By Diversifying Your Cover Crops With Legumes

Cover Cropping with Legumes

Farmers and ranchers are expert land stewards. Years ago, many producers began implementing conservation practices such as cover cropping with grass species. Cover crops improve soil health and help keep carbon “locked in.” If you’ve been managing fields with cover cropping, you can now qualify to participate in our carbon program by adding legumes to the species you plant.

At Agoro Carbon™, we help make sure including a legume species in your cover crop mix is not only agronomically beneficial, but also increases carbon sequestration potential.

Adding Legumes To The Mix

How it works:

- Choose the right species for your operation
- Determine the rate based on species selected
- Establish the application method
- Work together with your Agoro Carbon agronomist to address any concerns

Speak to your local Agoro Carbon cropping expert or agronomist for a custom evaluation of your operation.

Get (carbon) credit for your hard work

Carbon Performance-Based Payments:

Generating carbon credits comes with monetary payments. When you enroll in our carbon program by adding legumes to your cover crop, you'll receive payments based on carbon captured* by this practice.

The practices Agoro Carbon supports have been studied widely and many farms have been using them for decades. Our goal is to ensure that adopting conservation practices pays off in the long run, with benefits that add up.

*Payments made upon credit issuance, on tons captured above baseline results, after verification is complete in years 5 and 11.

“We are very excited to offer a way for legacy no-till and cover-crop farmers to be included in the carbon market, and show that while this market is still in its infancy, we are searching for ways to include and work with as many producers as possible.”

— Mark Worner, Sr. Support Agronomist & Farmer, Ohio

More Benefits Legumes Can Bring

Here's what a diverse cover crop including legumes can do for your land and your operation:

- Improve soil health
- Fracture compacted soils
- Deliver a potential increase in nitrogen efficiency
- Increase carbon capture
- Enhance crop resiliency to extreme weather events
- Provide operational cost savings (fewer passes; labor and fuel reductions)
- Improve crop nutrient availability
- Offer ecological benefits, including biodiversity and increased water quality and retention
